# Outline

#### Recurrent neural networks

- Recurrent neural networks
- Variants of RNN

#### 2 Advanced RNN Variants

- Challenge of long-term dependency
- Long Short-Term Memory (LSTM) Net
- Gated Recurrent Unit

# 3 Applications

# Sequential data

- Sequence of words in an English sentence
- Acoustic features at successive time frames in speech recognition
- Successive frames in video classification
- Rainfall measurements on successive days in Hong Kong
- Daily values of current exchange rate
- Nucleotide base pairs in a strand of DNA
- Instead of making independent predictions on samples, assume the dependency among samples and make a sequence of decisions for sequential samples

A B > A B >

э.

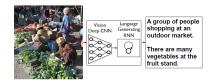

### Modeling sequential data

• Sample data sequences from a certain distribution

 $P(x_1,\ldots,x_T)$ 

• Generate natural sentences to describe an image

$$P(y_1,\ldots,y_T|I)$$

• Activity recognition from a video sequence

 $P(y|x_1,\ldots,x_T)$ 

э

#### Modeling sequential data

#### Generate natural sentences to describe a video

$$P(y_1,\ldots,y_{T'}|x_1,\ldots,x_T)$$

Language translation

$$P(y_1,\ldots,y_{T'}|x_1,\ldots,x_T)$$

Ulrich UNK, membre du conseil d'administration du constructeur automobile Audi, affirme qu'il s'agit d'une pratique courante depuis des années pour que les téléphones portables puissent être collectés avant les réunions du conseil d'administration afin qu'ils ne soient pas utilisés comme appareils d'écoute à distance.

Ulrich Hackenberg, membre du conseil d'administration du constructeur automobile Audi, déclare que la collecte des téléphones portables avant les réunions du conseil, afin qu'ils ne puissent pas être utilisés comme appareils d'écoute à distance, est une pratique courante depuis des années.

A B > A B >

#### Modeling sequential data

Use the chain rule to express the joint distribution for a sequence of observations

$$p(x_1,...,x_T) = \prod_{t=1}^T p(x_t|x_1,...,x_{t-1})$$

- Impractical to consider general dependence of future dependence on all previous observations  $p(x_t|x_{t-1},\ldots,x_0)$
- Complexity would grow without limit as the number of observations increases
- It is expected that recent observations are more informative than more historical observations in predicting future values

A B M A B M

### Markov models

- Markov models assume dependence on most recent observations
- First-order Markov model

$$p(x_1,...,x_T) = \prod_{t=1}^T p(x_t|x_{t-1})$$

• Second-order Markov model

$$p(x_1, \dots, x_T) = \prod_{t=1}^T p(x_t | x_{t-1}, x_{t-2})$$

▶ ★ 臣 ▶ …

### Hidden Markov Model (HMM)

- A classical way to model sequential data
- Sequence pairs  $h_1, h_2, \ldots, h_T$  (hidden variables) and  $x_1, x_2, \ldots, x_T$  (observations) are generated by the following process
  - Pick  $h_1$  at random from the distribution  $P(h_1).$  Pick  $x_1$  from the distribution  $p(x_1 \vert h_1)$
  - For t = 2 to T
    - Choose  $h_t$  at random from the distribution  $p(h_t|h_{t-1})$
    - Choose  $x_t$  at random from the distribution  $p(x_t|h_t)$
- The joint distribution is

$$p(x_1, \dots, x_T, h_1, \dots, h_T, \theta) = P(h_1) \prod_{t=2}^T P(h_t | h_{t-1}) \prod_{t=1}^T p(x_t | h_t)$$

< ∃ →

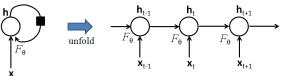

Recurrent neural networks Variants of RNN

#### Recurrent neural networks (RNN)

- HMM can be considered as a generative model while RNN is a discriminative model
- Model a dynamic system driven by an external signal  $x_t$

$$h_t = F_\theta(h_{t-1}, x_t)$$

•  $h_t$  contains information about the whole past sequence. The equation above implicitly defines a function which maps the whole past sequence  $(x_t, \ldots, x_1)$  to the current state  $h_t = G_t(x_t, \ldots, x_1)$ 

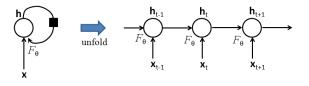

Left: Implementation of RNN, viewed as a circuit. The black square indicates a delay of 1 time step. Right: the same RNN viewed as an unfolded flow graph, where each node is now associated with one particular time step.

글 > : < 글 >

Recurrent neural networks Variants of RNN

#### Recurrent neural networks (RNN)

- The summary is lossy, since it maps an arbitrary length sequence  $(x_t,\ldots,x_1)$  to a fixed length vector  $h_t$
- Depending on the training criterion,  $h_t$  keeps some important aspects of the past sequence.
- Sharing parameters: the same weights are used for encoding feature representations (neuron responses) at different time steps
- A similar idea with CNN: replacing a fully connected network with local connections with parameter sharing
- It allows to apply the network to input sequences of different lengths and predicts sequences of different lengths

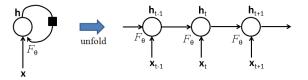

くぼう くほう くほう

Recurrent neural networks Variants of RNN

#### Recurrent neural networks (RNN)

- Sharing parameters for any sequence length allows more better generalization properties. If we have to define a different function  $G_t$  for each possible sequence length, each with its own parameters, we would not get any generalization to sequences of a size not seen in the training set
- One would need to see a lot more training examples, because a separate model would have to be trained for each sequence length

Recurrent neural networks Variants of RNN

## A vanilla RNN to predict sequences from input

$$P(y_1,\ldots,y_T|x_1,\ldots,x_T)$$

• Forward propagation equations, assuming that hyperbolic tangent non-linearities are used in the hidden units and softmax is used in output for classification problems

$$h_t = \tanh(W_{xh}x_t + W_{hh}h_{t-1} + b_h)$$
$$z_t = \operatorname{softmax}(W_{hz}h_t + b_z)$$
$$p(y_t = c) = z_{t,c}$$

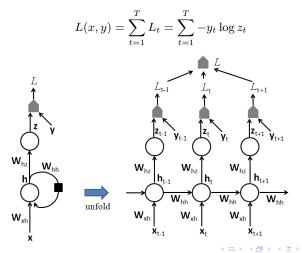

3 x 3

Recurrent neural networks Variants of RNN

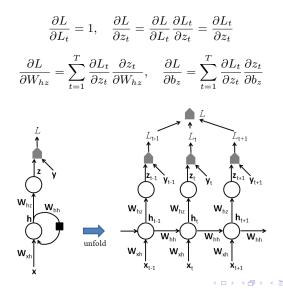

### **Overall Loss Function**

• The total loss for a given input/target sequence pair (x, y), measured by the cross entropy, is formulated as

Recurrent neural networks Variants of RNN

#### Gradients on $W_{hz}$ and $b_z$

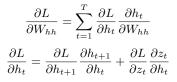

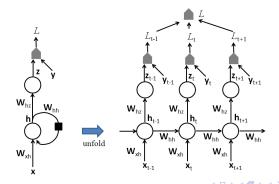

→ < ∃→

æ

Recurrent neural networks Variants of RNN

### Gradients on $W_{hh}$ and $W_{xh}$

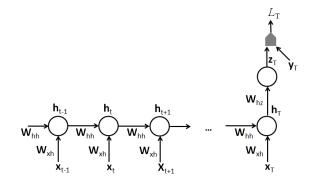

▶ < E >

æ

Recurrent neural networks Variants of RNN

#### Predict a single output at the end of the sequence

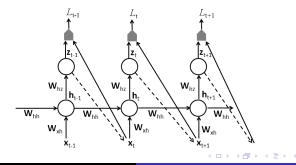

- Such a network can be used to summarize a sequence and produce a fixed-size representation used as input for further processing
- There might be a target right at the end or the gradient on the output  $z_t$  can be obtained by back-propagation from further downsteam modules

Recurrent neural networks Variants of RNN

Generative RNN modeling  $P(x_1, \ldots, x_T)$ 

- It can generate sequences from this distribution
- At the training stage, each  $x_t$  of the observed sequence serves both as input (for the current time step) and as target (for the previous time step)
- The output  $z_t$  encodes the parameters of a conditional distribution  $P(x_{t+1}|x_1,\ldots,x_t) = P(x_{t+1}|z_t)$  for  $x_{t+1}$  given the past sequence  $x_1,\ldots,x_t$

Recurrent neural networks Variants of RNN

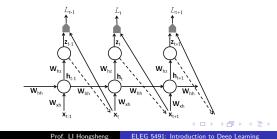

Generative RNN modeling  $P(x_1, \ldots, x_T)$ 

• Loss function: negative log-likelihood of x,  $L = \sum_t L_t$ 

$$P(x) = P(x_1, \dots, x_T) = \prod_{t=1}^T P(x_t | x_{t-1}, \dots, x_1)$$

$$L_t = -\log P(x_t | x_{t-1}, \dots, x_1)$$

• In generative mode,  $x_{t+1}$  is sampled from the conditional distribution  $P(x_{t+1}|x_1, \ldots, x_t) = P(x_{t+1}|z_t)$  (dashed arrows) and then that generated sample  $x_{t+1}$  is fed back as input for computing the next state  $h_{t+1}$ 

Recurrent neural networks Variants of RNN

### Generative RNN modeling $P(x_1, \ldots, x_T)$

- If RNN is used to generate sequences, one must also incorporate in the output information allowing to stochastically decide when to stop generating new output elements
- In the case when the output is a symbol taken from a vocabulary, one can add a special symbol corresponding to the end of a sequence
- One could also directly directly model the length T of the sequence through some parametric distribution.  $P(x_1, \ldots, x_T)$  is decomposed into

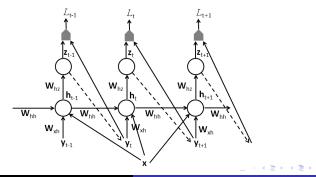

$$P(x_1,\ldots,x_T) = P(x_1,\ldots,x_T|T)P(T)$$

・ 同 ト ・ ヨ ト ・ ヨ ト

Recurrent neural networks Variants of RNN

### RNNs to represent conditional distributions P(y|x)

- If x is a fixed-sized vector, we can simply make it an extra input of the RNN that generates the y sequence. Some common ways of providing the extra input
  - as an extra input at each time step, or
  - as the initial state  $h_0$ , or
  - both
- Example: generate caption for an image

Recurrent neural networks Variants of RNN

## **Bidirectional RNNs**

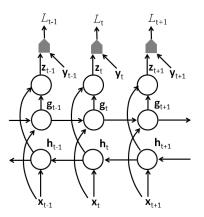

- In some applications, we want to output at time *t* a prediction regarding an output which may depend on the whole input sequence
  - In speech recognition, the correct interpretation of the current sound as a phoneme may depend on the next few phonemes because co-articulation and may depend on the next few words because of the linguistic dependencies between words
- Bidirectional recurrent neural network was proposed to address such need
- It combines a forward-going RNN and a backward-going RNN
- The idea can be extended to 2D input with four RNN going in four directions

・ 同 ト ・ ヨ ト ・ ヨ ト

Recurrent neural networks Variants of RNN

### **Bidirectional RNNs**

 $\bullet ~g_t$  summaries the information from the past sequence, and  $h_t$  summaries the information from the future sequence

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

### Difficulty of Learning Long-Term Dependencies

• Consider the gradient of a loss  $L_T$  at time T with respect to the parameter  $\theta$  of the recurrent function  $F_{\theta}$ 

$$h_t = F_{\theta}(h_{t-1}, x_t)$$
$$\frac{\partial L_T}{\partial \theta} = \sum_{t \le T} \frac{\partial L_T}{\partial h_T} \frac{\partial h_T}{\partial h_t} \frac{\partial F_{\theta}(h_{t-1}, x_t)}{\partial \theta}$$

 $\frac{\partial L_T}{\partial h_T}\frac{\partial h_T}{\partial h_t}\frac{\partial F_\theta(h_{t-1},x_t)}{\partial \theta} \text{ encodes long-term dependency when } T-t \text{ is large}$ 

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

## Difficulty of Learning Long-Term Dependencies

$$\frac{\partial h_T}{\partial h_t} = \frac{\partial h_T}{\partial h_{T-1}} \frac{\partial h_{T-1}}{\partial h_{T-2}} \cdots \frac{\partial h_{t+1}}{\partial h_t}$$

- Each layer-wise Jacobian  $\frac{\partial h_{t+1}}{\partial h_t}$  is the product of two matrices: (a) the recurrent matrix W and (b) the diagonal matrix whose entries are the derivatives of the non-linearities associated with the hidden units, which variy depending on the time step. This makes it likely that successive Jacobians have similar eigenvectors, making the product of these Jacobians explode or vanish even faster
- $\frac{\partial L_T}{\partial \theta}$  is a weighted sum of terms over spans [T, t], with weights that are exponentially smaller (or larger) for long-term dependencies relating the state at t to the state at T
- The signal about long term dependecies will tend to be hidden by the smallest fluctuations arising from short-term dependenties

ヘロン 人間 とくほう くほう

э

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

# Long Short-Term Memory (LSTM) Net

- LSTM introduces leaky units or forgetting mechanism
- The role of leaky units is to accumulate information over a long duration. However, once that information gets used, it might be useful for the neural network to forget the old state
  - For example, if a video sequence is composed as subsequences corresponding to different actions, we want a leaky unit to accumulate evidence inside each subsequence, and we need a mechanism to forget the old state by setting it to zero and starting to count from fresh when starting to process the next subsequence
- The forgetting rates are expected to be different at different time steps, depending on their previous hidden states and current input (conditioning the forgetting on the context)
- Parameters controlling the forgetting rates (not forgetting gates themselves) are learned from train data

э

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

# Long Short-Term Memory (LSTM) Net

- LSTMs also have this chain like structure, but the repeating module has a different structure
- Instead of having a single neural network layer, there are four, interacting in a very special way

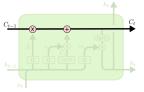

< (T) >

( )

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

# Long Short-Term Memory (LSTM) Net

• The key to LSTMs is the cell state. It's very easy for information to just flow along it unchanged.

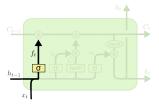

- The LSTM does have the ability to remove or add information to the cell state, carefully regulated by structures called gates
- Gates are a way to optionally let information through. They are composed out of a sigmoid neural net layer and a pointwise multiplication operation
- The sigmoid layer outputs numbers between zero and one, describing how much of each component should be let through. A value of zero means "let nothing through," while a value of one means "let everything through"

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

# Long Short-Term Memory (LSTM) Net

- The first step in our LSTM is to decide what information we are going to throw away from the cell state
- This decision is made by a sigmoid layer called the "forget gate layer." It looks at  $h_{t-1}$  and  $x_t$ , and outputs a number between 0 and 1 for each number in the cell state  $C_{t-1}$
- $\bullet$  A 1 represents "completely keep this" while a 0 represents "completely get rid of this"

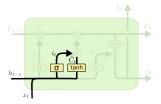

$$f_t = \sigma \left( W_f \cdot [h_{t-1}, x_t] + b_f \right)$$

▶ < ∃ >

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

# Long Short-Term Memory (LSTM) net

- The next step is to decide what new information we are going to store in the cell state
- First, a sigmoid layer called the "input gate layer" decides which values we'll update
- Next, a tanh layer creates a vector of new candidate values,  $C_t, \, {\rm that} \, {\rm could}$  be added to the state

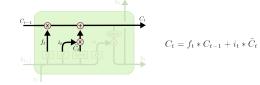

$$\begin{split} i_t &= \sigma \left( W_i \cdot [h_{t-1}, x_t] + b_i \right) \\ \tilde{C}_t &= \tanh(W_C \cdot [h_{t-1}, x_t] + b_C) \end{split}$$

∃ ► < ∃ ►</p>

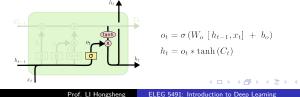

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

# Long Short-Term Memory (LSTM) net

• Now, it is time to update the old cell state,  $C_{t-1}$ , into the new cell state  $C_t$ 

- Finally, decide what are going to be output. This output will be based on our cell state, but will be a filtered version
- Run a sigmoid layer which decides what parts of the cell state we are going to output
- Put the cell state through tanh (to push the values to be between -1 and 1) and multiply it by the output of the sigmoid gate to output only a part

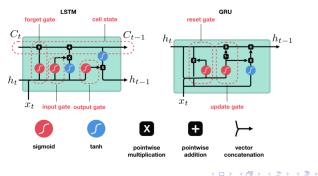

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

### Gated Recurrent Unit (GRU) network

- GRU abandons the cell state and used hidden state to transfer information. It also only has two gates, a reset gate and update gate
- Update gate: it helps the model to determine how much of the past information (from previous time steps) needs to be passed along to the future

$$z_t = \sigma(W_z x_t + U_z h_{t-1})$$

Challenge of long-term dependency Long Short-Term Memory (LSTM) Net Gated Recurrent Unit

## Gated Recurrent Unit (GRU) network

• **Reset gate:** it decides how much of the past information to forget when generating the new memory

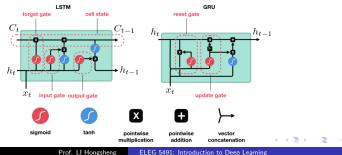

$$r_t = \sigma(W_r x_t + U_r h_{t-1})$$

New memory content is calculated as

$$h_t' = \tanh(Wx_t + r_t \odot Uh_{t-1})$$

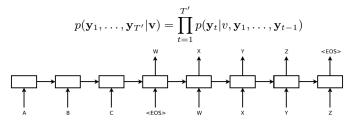

• Final memory at current time step: it determines what to collect from the current memory content  $h'_t$  and what from the previous steps  $h_{t-1}$ ?

$$h_t = z_t \odot h_{t-1} + (1 - z_t) \odot h'_t$$

Sequence-to-sequence language translation (Sutskever, Vinyals, and Le NIPS 2014)

- Model  $P(\mathbf{y}_1, \ldots, \mathbf{y}_{T'} | \mathbf{x}_1, \ldots, \mathbf{x}_T)$ . The input and output sequences have different lengths, are not aligned, and even do not have monotonic relationship
- Use one LSTM to read the input sequence  $(\mathbf{x}_1, \dots, \mathbf{x}_T)$ , one timestep at a time, to obtain a large fixed-dimensional vector representation  $\mathbf{v}$ , which is given by the last hidden state of the LSTM
- Then conditioned on v, a second LSTM generates the output sequence  $(y_1,\ldots,y_{T'})$  and computes its probability

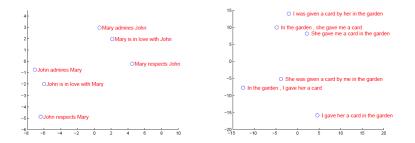

The model reads an input sentence "ABC" and produces "WXYZ" as the output sentence. The model stops making predictions after outputting the end-of-sentence token.  $\langle \Box \rangle \langle \Box \rangle \langle \Box \rangle \langle \Box \rangle \langle \Box \rangle \rangle \langle \Box \rangle$ 

#### Sequence-to-sequence language translation

- It requires each sentence ends with a special end-of-sequence symbol "<EOS>", which enables the model to define a distribution over sequences of all possible lengths
- It is valuable to reverse the order of the words of the input sequence for decoding. For example, instead of mapping the sentence a, b, c to the sentence α, β, γ, the LSTM is asked to map c, b, a to α, β, γ, where α, β, γ is the translation of a, b, c.
- This way, a is in close proximity to α, b is fairly close to β, and so on, a fact that makes it easy for stochastic gradient descent to "establish communication" between the input and the output. It introduces many short term dependencies in the data that make the optimization problem much easier.

< 回 > < 回 > < 回 > …

#### Sequence-to-sequence language translation

The figure shows a 2-dimensional PCA projection of the LSTM hidden states that are obtained after processing the phrases in the figures. The phrases are clustered by meaning, which in these examples is primarily a function of word order, which would be difficult to capture with a bag-of-words model. The figure clearly shows that the representations are sensitive to the order of words, while being fairly insensitive to the replacement of an active voice with a passive voice.

문어 세 문어

### Generate image captions (Vinyals et al. arXiv 2014)

- Use a CNN as an image encoder and transform it to a fixed-length vector
- It is used as the initial hidden state of a "decoder" RNN that generates the target sequence

글 🖌 🔺 글 🛌

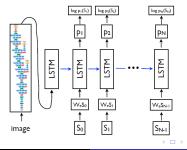

## Generate image captions

• The learning process is to maximize the probability of the correct description given the image

$$\theta^* = \arg \max \sum_{(I,S)} \log P(S|I;\theta)$$

$$\log P(S|I) = \sum_{t=0}^{N} \log P(S_t|I, S_0, \dots, S_{t-1})$$

 ${\bf I}$  is an image and  ${\bf S}$  is its correct description

3 x 3

#### Generate image captions

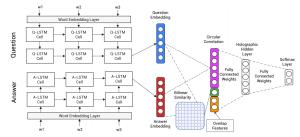

- Denote by  $S_0$  a special start work and by  $S_N$  a special stop word
- Both the image and the words are mapped to the same space, the image by using CNN, the words by using word embedding  $W_e$
- The image  ${\cal I}$  is only input once to inform the LSTM about the image contents
- Sampling: sample the first word according to  $P_1$ , then provide the corresponding embedding as input and sample  $P_2$ , continuing like this until it samples the special end-of-sentence token

$$x_{-1} = \text{CNN}(\mathbf{I})$$
$$x_t = W_e S_t, t \in \{0, \dots, N-1\}$$
$$P_{t+1} = \text{LSTM}(x_t), t \in \{0, \dots, N-1\}$$
$$L(I, S) = -\sum_{t=1}^N \log P_t(S_t)$$
